ABSTRACT: Microthermometric studies in gangue quartz from the Asimotrypes mesothermal gold deposit indicate early ore deposition at P-T conditions of 275^oC-310^oC and 2.7-3.1 kb during unmixing of the mineralizing fluids. This was followed by deposition at temperatures down to 130^oC and low near-surface pressures. Whole rock O ($\delta^{18}\text{O}$: 15.79 to 16.48 per mil) and H (δD : -105 to -125 per mil) isotope data suggest that mineralizing fluids are of meteoric origin perhaps incorporating a metamorphic fluid component. Fluid inclusion and stable isotope data of the Asimotrypes gold mineralization are consistent with genesis from deeply connecting meteoric water driven by regional uplift through rocks undergoing retrogressive greenschist facies metamorphism.

1 GEOLOGICAL SETTING

The Asimotrypes mesothermal gold deposit is located in the Pangeon Mt. (E. Macedonia, N. Greece) which geologically is part of the western Rhodope metamorphic province (RMP). The rocks of the western part of the RMP that crop out between the Strymon and Nestos Rivers, and include Pangeon Mt). They represent the metamorphic core complex of an Alpine collisional orogen, that was extended and tectonically unroofed in the footwall of the Strymon Valley detachment system beginning in Middle Miocene time (Dinter, 1994, 1998). These rocks comprise mainly marbles, gneisses, and schists of Paleozoic to Mesozoic age intruded by Oligocene granodiorites. Alpine metamorphism (Upper Cretaceous-Middle Eocene) reached upper greenschist to lower amphibolite conditions ($T=550^{\circ}\text{C}$ - 600°C , $P=13.5$ - 15 bar). A low pressure, greenschist facies ($T=350^{\circ}\text{C}$ - 400°C , $P=3$ - 5 bar) retrograde overprint during uplift marked the end of Alpine metamorphism in Miocene (Mposkos, 1994). Post-metamorphic Miocene uplift has been recognized in the Pangeon Mt and it was ascribed to Late Cenozoic extensional tectonics (Wawzenitz et al., 1994).

2 MINERALIZATION

Mineralization occurs in irregular quartzite pods or lenses developed in marble along the contact with schists (replacement style), and quartz veins cross-cutting the marble (shear-zone style). The Asimotry-

pes ore consists mainly of arsenopyrite, pyrite and gold, with subordinate sphalerite, galena, chalcopyrite, pyrrhotite, tetrahydrite-tennantite, marcasite, covellite and malachite. Gold is either refractory occurring mainly in arsenopyrite and to a lesser extent in As-pyrite, or free in the oxide minerals. Gangue minerals include dominantly quartz and lesser muscovite-sericite. Mineralization bears evidence of ductile deformation followed by brittle fracturing, cataclasis and recrystallization. Quartz exhibits wavy extinction and suture margins (quartz A). Sub-grains of quartz (quartz B) locally surround quartz A. Cataclastic arsenopyrite is also of local development. Textural observations suggest that quartz A and gold-bearing arsenopyrite have coprecipitated.

3 FLUID INCLUSIONS

All the fluid inclusions studied are hosted by quartz A and healed microfractures. No workable inclusions were found in quartz B. Three types of fluid inclusions (with subtypes) were recognized based on constituent phases at room temperature and microthermometric behavior.

Type I. H₂O-CO₂ 3-phase inclusions: L₁ (H₂O)+L₂ (CO₂)+V (CO₂). They are characterized by highly variable CO₂/H₂O volumetric ratios. Type I are subdivided into Type Ia, H₂O-rich inclusions (10-40 volume % CO₂) which homogenize to the liquid (aqueous) phase, and Type Ib, CO₂-rich inclusions (70-90.

volume % CO₂) which homogenize to the vapor (carbonic) phase

Type II. Aqueous 2-phase inclusions: L+V. These contain an aqueous liquid and an aqueous vapor phase occupying 10-20 % of the inclusion volume. They always homogenize to the liquid phase.

Type III. Naturally decrepitated and/or leaked inclusions: V or L+V. Decrepitated inclusions are either empty or contain a vapor phase, whereas leaked varieties exhibit inconsistent vapor/liquid ratios.

Type I inclusions occur in clear domains of the quartz matrix. Type II occupy healed trans-granular microfractures, and Type III inclusions occur either isolated in quartz A or at the interfaces of quartz B. Type III inclusions have been swept to the quartz grain boundaries as they migrated through the strained crystal, and represent early ruptured inclusions. This disruption was caused by internal overpressures. The shape of inclusion Types I and II is elliptical to sub-rounded with smooth boundaries. Their sizes vary from <5 to 20 μm. Type III inclusions are up to 50 μm in size and range from irregular through elongate to ovoid in shape.

Textural relationships suggest that the fluids represented by Types I and II are related to the ore-forming event, and Type III related to syndepositional decompression of the host quartz during uplift.

4 FLUID IMMISCIBILITY AND P-T CONDITIONS OF MINERALIZATION

Homogenization temperatures range between 275°C and 335°C for Type Ia inclusions, and between 308°C and 340°C for Type Ib inclusions. Coexisting Types Ia and Ib inclusions homogenizing over the same temperature range and producing different phases indicate the existence of a fluid that has undergone phase separation prior to or during entrapment as fluid inclusions (Ramboz et al., 1982). The variable phase ratios of Type I inclusions is probably a result of mixed entrapment of variable physical proportions of immiscible H₂O-rich and CO₂-rich components. Considering that for coeval inclusions, the minimum temperatures for inclusion homogenization into the aqueous and into the carbonic phases are provided by inclusions trapping pure end-members. In the studied inclusions minimum homogenization P and T conditions of 275°-310°C at calculated pressures between 2.7 and 3.1 kb can be considered as conditions of phase unmixing and deposition of the majority of the mineralization.

Estimated salinities of Type Ia inclusions (2.6-7.3 wt % NaCl equiv.) increase with decreasing temperature while salinities of Type Ib inclusions (0.61-2.2 wt % NaCl equiv.) show opposite trend. This is a result of preferential partitioning of salt into the H₂O-rich liquid phase rather than into the CO₂-rich vapor phase during unmixing (Fig. 1) (Bowers and Helgeson, 1983). Type II inclusions show a trend of decreasing salinity (5.6-9 wt % NaCl equiv.) with homogenization temperature (135°-256°C) (Fig.1). This

Figure 1. Total homogenization temperatures versus salinity diagram for fluid inclusions from the Asimotrypes ore. CO₂-rich and H₂O-rich inclusions represent unmixing of a low salinity H₂O-CO₂ fluid, whereas secondary fluids record later fluid incursion of more dilute waters.

trend in conjunction with their occurrence along late healed fractures and stable isotope data (see below) indicate flashing of cooler meteoric waters into the mineralizing system during brittle fracturing induced by syn- to post-metamorphic uplift. Mineralizing fluid temperatures and pressures approach closely those of regional retrogressive greenschist facies metamorphism (T=350^o-400^oC, P=3-5 kb) (Fig. 2), and attest to the conditions of syn- to post-metamorphic cooling.

5 WHOLE ROCK OXYGEN AND HYDRO- GEN ISOTOPES

Whole rock $\delta^{18}\text{O}$ values for the Asimotrypes ore lie within a narrow range from 15.79-16.48 per mil with a median value of 16.15 ± 0.26 (1 σ). It is apparent that these values are consistent with values of metamorphic fluids. δD values are in the range of -105 to -125 per mil with a median value of -117 ± 7.5 (1 σ). These values imply that all fluids contained in the Asimotrypes ore represent evolved meteoric waters (Shelton et al., 1988; Nesbitt et al., 1989).

Figure 3 shows that the area in δD - $\delta^{18}\text{O}$ space occupied by the Asimotrypes fluids lie outside the metamorphic and magmatic water fields and could be only derived from these fluids through a significant negative shift in the $\delta\text{D}_{\text{fluid}}$ values. It is suggested therefore, that the Asimotrypes mineralizing fluids are of meteoric origin, perhaps incorporating a metamorphic fluid component, and that the observed fluid composition was derived by substantial interaction of this fluid with the rock mass.

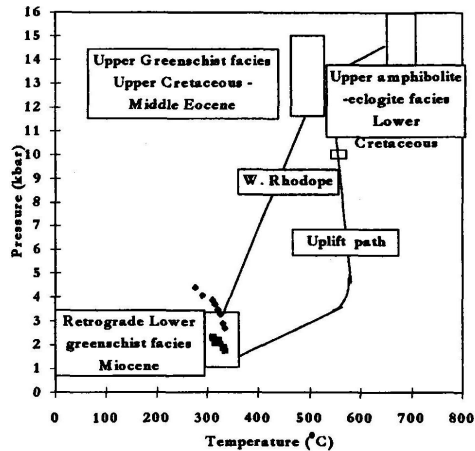

Figure 2. Pressure-temperature diagram showing calculated homogenization conditions for Type I and II inclusions, showing their relationship to regional metamorphic conditions in the Rhodope Massif.

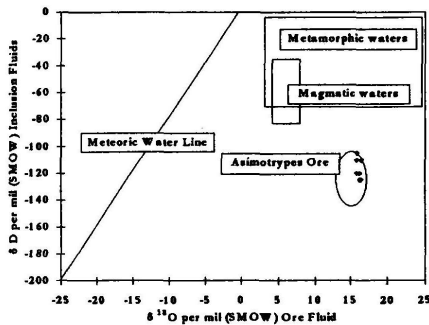

Figure 3. Plot of δD inclusion fluids versus $\delta^{18}\text{O}$ fluids of the Asimotrypes mesothermal gold deposit. The isotopic composition of the Asimotrypes fields clearly lies outside of the metamorphic and magmatic water fields.

6 CONCLUSIONS

1. Mineralizing fluid pressures and temperatures indicate early ore deposition during phase separation at temperatures between 275^o and 310^oC at calculated pressures between 2.7 and 3.1 kb followed by late deposition at temperatures down to 130^oC and very low near-surface pressures.
2. The Asimotrypes mineralizing fluids are of meteoric origin, perhaps incorporating a metamorphic fluid component.
3. Combined with geological evidence, the fluid inclusion and stable isotope data of the Asimotrypes gold mineralization are consistent with genesis from deeply convecting meteoric water driven by regional

uplift through rocks undergoing retrogressive greenschist facies metamorphism.

Mineral deposits: Research and exploration - where do they meet? - *Proceedings of the fourth biennial SGA Meeting, Turku, Finland, 11-13 August 1997*

1997, 25 cm, 1008 pp., EUR 137.50 / \$162.00 / £97

This volume contains 246 extended abstracts of the Meeting and they offer an interesting state-of-the-art review of ongoing research in the many aspects of economic geology related to exploration. Topics including organics and mineral deposits, gold and precious metal deposits, submarine hydrothermal processes and mineralizations, mineral deposits in mafic and ultramafic rocks, mineral deposits in sedimentary environments, granites and ore formation, industrial mineral deposits, diamond deposits and exploration, metamorphism and ore deposits, mineral deposit modelling in exploration, environmental aspects of mineral deposits.

Aggregate resources - A global perspective

1998, 25 cm, 480 pp., EUR 86.00 / \$99.00 / £60

Provides a comprehensive collection of 27 diverse scientific papers on aggregate topics such as geology of deposits, geophysical exploration techniques, deposit prediction and modeling, land-use case studies, production values and trends, geotechnical properties, legislation politics and others. This diversity in subject matter is further enhanced by relying on contributions from a number of countries including Australia, Belgium, Canada, Lebanon, Netherlands, Norway, South Africa, United Kingdom and the United States. The book will appeal to all those involved with aggregate resources: Geologists, producers, technicians, construction engineers, developers, land-use planners, legislators, academics & the public consumer, especially since all of us are in some manner, directly dependent or indirectly affected by this resource.

*Each chapter is a study on a particular area of importance for aggregate producers. *Pit & Quarry*, April 1998.

*Strongly recommended to engineers in the disciplines of mechanical, aerospace & electrical engineering. *Structural Engineer*, 1999.

Mica and mica industry

1995, 24 cm, 212 pp., EUR 88.00 / \$104.00 / £62

(No rights India)

Mica is one of the strategic minerals. On account of its unique and excellent insulating properties and its high heat-resistance capacity, it is indispensable in the electrical & electronics industries. The book brings together all possible information on the subject of 'mica' in a comprehensive & scientific manner so that present day as well as future manufacturers and users should benefit from this treatise. Aspects treated are world trade, production, geology, prospecting, mining, as well as other scientific technological advancements relating to the commodity.

Geochemistry, mineralogy and genesis of gold deposits

1996, 24 cm, 344 pp., EUR 93.50 / \$110.00 / £66

(No rights India)

A translation of 'Geokimiya mineralogiya i genezis zolotrudnikh mestorozhdenii', Moscow. The behavior of gold in sedimentary, magmatic and postmagmatic processes are studied and 40 gold-bearing minerals including ten which were recently discovered are described. The results are presented of new experimental studies on phase relations in gold-sulfide systems. The solubility & form of gold migration in high-temperature chloride, sulfide and arsenic solutions are determined. Based on the new data, the genesis of gold deposits is studied and a geochemical classification proposed. This book is designed for specialists in the field of gold chemistry, geochemistry and mineralogy and for field geologists surveying and prospecting for gold.

Geoenvironment: An introduction

1995, 25 cm, 292 pp., EUR 85.00 / \$99.00 / £60

(No rights India)

The focus of the book is on the management of the geoenvironment. It seeks to explain how through an understanding of the environmental processes that take place in rocks, soils, waters, sediments, air, etc. the resources contained in them could be managed sustainably. It provides a balanced coverage of the environmental problems of both the North (e.g. chemical pollution and waste management) and the South (e.g. land degradation and water scarcity).

*The text is clear and lucid, and is copiously illustrated...

The book fulfills the need for a modern, broad spectrum, college-level textbook / reference book on geoenvironment, and is warmly recommended. *Envir. Geology, Vol.28, no.1, July 1996.*

*This book is a good resource for environmental scientists and policy makers. *EOS, Vol.49(7), 1998.*
