## Abstract

For every  $r \in \mathbb{N}$ , we denote by  $\theta_r$  the multigraph with two vertices and  $r$  parallel edges. Given a graph  $G$ , we say that a subgraph  $H$  of  $G$  is a *model of  $\theta_r$  in  $G$*  if  $H$  contains  $\theta_r$  as a contraction. We prove that the following edge variant of the Erdős-Pósa property holds for every  $r \geq 2$ : if  $G$  is a graph and  $k$  is a positive integer, then either  $G$  contains a packing of  $k$  mutually edge-disjoint models of  $\theta_r$ , or it contains a set  $S$  of  $f_r(k)$  edges meeting all models of  $\theta_r$  in  $G$ , for both  $f_r(k) = O(k^2 r^3 \text{polylog } kr)$  and  $f_r(k) = O(k^4 r^2 \text{polylog } kr)$ .

*Keywords:* Erdős-Pósa property, packings in graphs, coverings in graphs

## 1. Introduction

Typically, an Erdős-Pósa property reveals relations between covering and packing invariants in combinatorial structures. The origin of the study of such properties comes from the Erdős-Pósa Theorem [5], stating that there is a function  $f : \mathbb{N} \rightarrow \mathbb{N}$  such that for every  $k \in \mathbb{N}$  and for every graph  $G$ , either  $G$  contains  $k$  vertex-disjoint cycles, or there is a set  $X$  of  $f(k)$  vertices in  $G$  meeting all cycles of  $G$ . In particular, Erdős and Pósa proved this result for  $f(k) = O(k \cdot \log k)$ .

An interesting line of research aims at extending Erdős-Pósa Theorem for packings and coverings of more general graph structures. In this direction, we say that a graph class  $\mathcal{G}$  *satisfies the Erdős-Pósa property* if there exists a function  $f_{\mathcal{G}} : \mathbb{N} \rightarrow \mathbb{N}$  such that, for every graph  $G$  and every positive integer  $k$ , either  $G$  contains  $k$  mutually vertex-disjoint

subgraphs, each isomorphic to a graph in  $\mathcal{G}$ , or it contains a set  $S$  of  $f_{\mathcal{G}}(k)$  vertices meeting every subgraph of  $G$  that is isomorphic to a graph in  $\mathcal{G}$ . When this property holds for a class  $\mathcal{G}$ , we call the function  $f_{\mathcal{G}}$  *the gap of the Erdős-Pósa property for the class  $\mathcal{G}$* . In this sense, the classic Erdős-Pósa Theorem says that the class containing all cycles satisfies the Erdős-Pósa property with gap  $O(k \cdot \log k)$ .

Given a graph  $J$ , we denote by  $\mathcal{M}(J)$  the set of all graphs containing  $J$  as a contraction. Robertson and Seymour proved the following proposition, which in particular can be seen as an extension of the Erdős-Pósa Theorem.

**Proposition 1.** *Let  $J$  be a graph. The class  $\mathcal{M}(J)$  satisfies the Erdős-Pósa property if and only if  $J$  is planar.*

A proof of Proposition 1 appeared for the first time in [18]. Another proof can be found in Diestel’s monograph [4, Corollary 12.4.10 and Exercise 40 of Chapter 12]. In view of Proposition 1, it is natural to try to derive good estimations of the gap function  $f_{\mathcal{M}(J)}$  in the case where  $J$  is a planar graph. In this direction, the recent breakthrough results of Chekuri and Chuzhoy imply that  $f_{\mathcal{M}(J)}(k) = k \cdot \log^{O(1)} k$  [2] and, even more, that  $f_{\mathcal{M}(J)} = (k + |V(J)|)^{O(1)}$  [3]. Before this, the best known estimation of the gap for planar graphs was exponential, namely  $f_{\mathcal{M}(J)}(k) = 2^{O(k \log k)}$ , and could be deduced from [14] using the proof of [18]. Moreover, some improved polynomial gaps have been proven for particular instantiations of the graph  $J$  (see [6–9, 15, 16]). Another direction is to add restrictions on the graphs  $G$  that we consider, which usually allows to optimize the gap  $f_{\mathcal{M}(J)}$ . In this direction, it is known that  $f_{\mathcal{M}(J)} = O(k)$  in the case where graphs are restricted to some non-trivial minor-closed class [10].

We consider the edge counterpart of the Erdős-Pósa property, where packings are edge-disjoint (instead of vertex-disjoint) and coverings contain edges instead of vertices. We say that a graph class  $\mathcal{G}$  satisfies *the edge variant of the Erdős-Pósa property* if there exists a function  $f_{\mathcal{G}}$  such that, for every graph  $G$  and every positive integer  $k$ , either  $G$  contains  $k$  mutually edge-disjoint subgraphs, each isomorphic to a graph in  $\mathcal{G}$ , or it contains a set  $X$  of  $f_{\mathcal{G}}(k)$  edges meeting every subgraph of  $G$  that is isomorphic to a graph in  $\mathcal{G}$ . Recently, the edge variant of the Erdős-Pósa property was proved in [12] for 4-edge-connected graphs in the case where  $\mathcal{G}$  contains all odd cycles.

Figure 1: The graph  $\theta_5$ .

In this paper we concentrate on the case where  $\mathcal{G} = \mathcal{M}(J)$  for some graph  $J$ . We find it an interesting question whether an edge-analogue of Proposition 1 exists or not. To our knowledge, the only case for which  $\mathcal{M}(J)$  satisfies the edge variant of the Erdős-Pósa property is when  $J = K_3$ , *i.e.* when the class of graphs  $\mathcal{G}$  contains all cycles. This result is the edge-counterpart of the Erdős-Pósa Theorem and appears as a (hard) exercise in [4, Exercice 23 of Chapter 7]. For every  $r \geq 2$ , let  $\theta_r$  be the graph containing two vertices and  $r$  multiple edges between them (see Figure 1). The results of this paper can be stated as follows:

**Theorem 1.** *The edge variant of the Erdős-Pósa property holds for  $\mathcal{M}(\theta_r)$  with gap  $f_{\mathcal{M}(\theta_r)}$ , with*

$$f_{\mathcal{M}(\theta_r)}(k) = O(k^2 r^3 \text{polylog } kr) \quad \text{and} \quad f_{\mathcal{M}(\theta_r)}(k) = O(k^4 r^2 \text{polylog } kr).$$

Theorem 1 is the edge-counterpart of the main result of [9]. The proof is presented in Section 3 and contains three main ingredients. The first is a reduction of the problem to graphs of bounded degree, presented in Section 3.1. The second is an application of recent results of [2] to obtain bounds on the treewidth of the graphs we consider (Section 3.2) and the last is an extension of the techniques in [10] fitting our needs, which is presented in Section 3.3. Section 2 contains definitions and preliminary results and Section 4 discusses further research about the problem investigated in this paper.

## 2. Definitions and preliminaries

For any graph  $G$ ,  $V(G)$  (respectively  $E(G)$ ) denotes the *set of vertices* (respectively *edges*) of  $G$ . Even when dealing with multigraphs (*i.e.* graphs where more than one edge is allowed between two vertices) we will use the term *graph*. A graph  $G'$  is a *subgraph* of a graph  $G$  if  $V(G') \subseteq V(G)$  and  $E(G') \subseteq E(G)$ , and we denote this by  $G' \subseteq G$ . If  $X$  is a subset of  $V(G)$  (respectively  $E(G)$ ), we denote by  $G[X]$  the *subgraph of  $G$  induced by  $X$* , *i.e.* the graph with vertex set  $X$  (respectively  $\cup_{e \in X} e$ ) and edge set  $\{\{x, y\} \in E(G), x \in X \text{ and } y \in X\}$  (respectively  $X$ ). If  $S$  is a subset of vertices or edges of a graph  $G$ , the graph  $G \setminus S$  is the graph obtained from  $G$  after the removal of the elements of  $S$ . For every vertex  $v \in V(G)$  the neighborhood of  $v$  in  $G$ , denoted by  $N_G(v)$ , is the subset of vertices that are adjacent to  $v$ , and its size is called the *degree* of  $v$  in  $G$ , written  $\deg_G(v)$ . The maximum degree  $\Delta(G)$  of a graph  $G$  is the maximum value taken by  $\deg_G$  over  $V(G)$ . Given a non-negative integer  $k$ , a triple  $(V_1, S, V_2)$  is called a  *$k$ -separation triple* of a graph  $G$  if  $|S| \leq k$  and  $\{V_1, S, V_2\}$  is a partition of  $V(G)$  such that there is no edge between a vertex of  $V_1$  and a vertex of  $V_2$ . Unless otherwise stated, logarithms are binary. For any two integers  $a, b$  such that  $a \leq b$ , the notation  $\llbracket a, b \rrbracket$  stands for the set of integers  $\{a, a + 1, \dots, b\}$ . In a tree  $T$ , rooted at a vertex  $r \in V(T)$ , a vertex  $u \in V(T)$  is said to be a *descendant* of a vertex  $v \neq u$  if the path in  $T$  from  $r$  to  $u$  contains  $v$ . The set of descendants of  $v$  is denoted by  $\text{desc}_T(v)$ .

*Minors and models.* In a graph  $G$ , a *contraction* of an edge  $e = \{u, v\} \in E(G)$  is the operation that removes  $e$  from  $G$  and identifies the vertices  $u$  and  $v$ . In this paper, we keep multiple edges that may appear between two vertices after a contraction (for instance, contracting an edge in a triangle gives a graph with two vertices connected by two edges). For any graph  $J$ , let  $\mathcal{M}(J)$  denote the class of *contraction models* (models for short) of  $J$ , *i.e.* the class of graphs that can be contracted to  $J$ . We say that a graph  $J$  is *minor* of a graph  $G$  (denoted by  $J \leq_m G$ ) if a subgraph of  $G$  is a model of  $J$  ( $J$ -*model* for short), or, equivalently, if  $J$  can be obtained from  $G$  by a series of vertex deletions, edge deletions, and edge contractions.

*Packings and coverings.* Let  $G$  and  $J$  be graphs. We denote by  $\mathbf{pack}_J^{\mathcal{V}}(G)$  the maximum number of vertex-disjoint models of  $J$  in  $G$  and by  $\mathbf{cover}_J^{\mathcal{V}}(G)$  the minimum size of a subset  $S \subseteq V(G)$  (called  $J$ -*vertex-hitting set*) that meets the vertex sets of all models of  $J$  in  $G$ . These invariants are widely studied in the context of the classic Erdős-Pósa property.

Similarly, we write  $\mathbf{pack}_J^{\mathcal{E}}(G)$  for the maximum number of edge-disjoint models of  $J$  in  $G$  and  $\mathbf{cover}_J^{\mathcal{E}}(G)$  for the minimum size of a subset  $S \subseteq E(G)$  (called  $J$ -*edge-hitting set*) that meets the edge sets of all models of  $J$  in  $G$ . Obviously, for every two graphs  $G$  and  $J$ , the following inequality holds:

$$\mathbf{pack}_J^{\mathcal{E}}(G) \leq \mathbf{cover}_J^{\mathcal{E}}(G).$$

A graph  $J$  is said to satisfy the *(vertex-)Erdős-Pósa property for minors* (*vertex-Erdős-Pósa property* for short) if there is a function  $f_J: \mathbb{N} \rightarrow \mathbb{N}$ , called *vertex-Erdős-Pósa gap* of  $J$ , satisfying

$$\mathbf{cover}_J^{\mathcal{V}}(G) \leq f_J(\mathbf{pack}_J^{\mathcal{V}}(G)).$$

The research of this paper is motivated by the course of detecting graphs  $J$  for which there is a function  $h_J: \mathbb{N} \rightarrow \mathbb{N}$  satisfying the following inequality for every graph  $G$ :

$$\mathbf{cover}_J^{\mathcal{E}}(G) \leq h_J(\mathbf{pack}_J^{\mathcal{E}}(G)). \tag{1}$$

Such graphs are said to satisfy the *edge variant of the Erdős-Pósa property for minors* (or, in short, the *edge-Erdős-Pósa property*) and the function  $h_J$  is called the *gap* of the edge-Erdős-Pósa property for  $J$  (*edge-Erdős-Pósa gap* for short). This definition is an edge-counterpart to the existing Erdős-Pósa property and (vertex-)Erdős-Pósa gap.

*Treewidth.* A *tree decomposition* of a graph  $G$  is a pair  $(T, \mathcal{V})$  where  $T$  is a tree and  $\mathcal{V}$  a family  $(V_t)_{t \in V(T)}$  of subsets of  $V(G)$  (called *bags*) indexed by the vertices of  $T$  and such that

- (i)  $\bigcup_{t \in V(T)} V_t = V(G)$ ;
- (ii) for every edge  $e$  of  $G$  there is an element of  $\mathcal{V}$  containing both endpoints of  $e$ ; and

(iii) for every  $v \in V(G)$ , the subgraph of  $T$  induced by  $\{t \in V(T) \mid v \in V_t\}$  is connected.

The *width* of a tree decomposition  $T$  is defined as  $\max_{t \in V(T)} |V_t| - 1$  (that is, the maximum size of a bag minus one). The *treewidth* of  $G$ , written  $\mathbf{tw}(G)$ , is the minimum width of any of its tree decompositions.

A tree decomposition  $(T, \mathcal{V})$  of a graph  $G$  is said to be a *nice* tree decomposition if

- (i) every vertex of  $T$  has degree at most 3;
- (ii)  $T$  is rooted at one of its vertices  $r$  whose bag is empty ( $V_r = \emptyset$ ); and
- (iii) every vertex  $t$  of  $T$  is
  - either a *base node*, *i.e.* a leaf of  $T$  whose bag is empty ( $V_t = \emptyset$ ) and different from the root;
  - or an *introduce node*, *i.e.* a vertex with only one child  $t'$  such that  $V_{t'} = V_t \cup \{u\}$  for some  $u \in V(G)$ ;
  - or a *forget node*, *i.e.* a vertex with only one child  $t'$  such that  $V_t = V_{t'} \cup \{u\}$  for some  $u \in V(G)$ ;
  - or a *join node*, *i.e.* a vertex with two child  $t_1$  and  $t_2$  such that  $V_t = V_{t_1} = V_{t_2}$ .

It is known that every graph has an optimal tree decomposition which is nice [13].

*The graph  $\theta_r$  and the Erdős-Pósa property..* The vertex-Erdős-Pósa property of  $\theta_r$  received some attention, in particular in [7, 9, 11]. For instance the main result of [9] is the following estimation of the vertex-Erdős-Pósa gap for  $\mathcal{M}(\theta_r)$ .

**Proposition 2** ([9]). *For every  $r \in \mathbb{N}^*$ ,  $\theta_r$  has the vertex-Erdős-Pósa property with gap  $O(k^2)$ .*

By a careful analysis of the size of a  $\mathcal{M}(\theta_r)$ -hitting set presented in [9] (c.f. Lemma 6), the estimation of the gap of Proposition 2 can be made quadratic in both  $k$  and  $r$ . From this, we can derive a  $O(k^3 r^3)$  edge-Erdős-Pósa gap for  $\mathcal{M}(\theta_r)$  (Corollary 2) by using our Lemma 7 that makes possible to translate a  $\mathcal{M}(\theta_r)$ -vertex-hitting set into a  $\mathcal{M}(\theta_r)$ -edge-hitting set.

However, Theorem 1 gives better estimations of this gap, either in  $k$  or in  $r$ .

*Patterns in graphs of big treewidth..* In the following section, we will use several propositions asserting that every graph  $G$  of treewidth at least  $c_H$  contains some fixed graph  $H$  as a minor, where the constant  $c_H$  depends on  $H$ . For instance, we will show in Lemma 6 a simple relation between the constant  $c_{k, \theta_r}$  and the vertex-Erdős-Pósa gap for  $\theta_r$ . These propositions as stated thereafter.

**Proposition 3** ([17, Lemma 3.2]). *For every integer  $r \geq 1$  and graph  $G$ , if  $\mathbf{tw}(G) \geq 2r - 1$  then  $G \leq_m \theta_r$ .*

**Proposition 4** ([9, Lemma 1], see also [1]). *Let  $k$  and  $r$  be two positive integers. For every graph  $G$ , if  $\mathbf{tw}(G) \geq 2k^2r^2$  then  $G$  contains at least  $k$  vertex-disjoint models of  $\theta_r$ .*

**Proposition 5** ([2, Theorem 1.1]). *There is a function  $f_{\text{Prop5}}(t) = O(\text{polylog } t)$  such that, for every graph  $G$  and every positive integers  $h$  and  $p$ , if  $hp^2 \leq \frac{\mathbf{tw}(G)}{f_{\text{Prop5}}(\mathbf{tw}(G))}$ , there is a partition  $G_1, \dots, G_h$  of  $G$  into vertex-disjoint subgraphs such that  $\mathbf{tw}(G_i) \geq p$  for each  $i \in [1, h]$ .*

**Proposition 6** ([2, Theorem 1.2]). *There is a function  $f_{\text{Prop6}}(t) = O(\text{polylog } t)$  such that, for every graph  $G$  and every positive integers  $h$  and  $p$ , if  $h^3p \leq \frac{\mathbf{tw}(G)}{f_{\text{Prop6}}(\mathbf{tw}(G))}$  then there is a partition  $G_1, \dots, G_h$  of  $G$  into vertex-disjoint subgraphs such that  $\mathbf{tw}(G_i) \geq p$  for each  $i \in [1, h]$ .*

### 3. The edge-Erdős-Pósa property for graphs $\theta_r$

#### 3.1. Bounding the degree

In the sequel, we deal with graphs in which some vertices are marked. If  $G$  is a graph and  $m: V(G) \rightarrow \{0, 1\}$  is a function, we say that  $(G, m)$  is a graph *marked* by  $m$ . A vertex  $v$  of  $G$  such that  $m(v) = 1$  is said to be *marked*. We denote by  $\mu$  the function that, given a graph, returns its number of marked vertices. We now define an  $r$ -good partition. Given a positive integer  $r$ , a marked tree  $(T, m)$  is said to have an  $r$ -good partition of root  $v$  if there is a pair  $((T_1, m_1), (T_2, m_2))$  of marked trees such that:

- (i)  $T_1$  and  $T_2$  are subtrees of  $T$  such that  $(E(T_1), E(T_2))$  is a partition of  $E(T)$ ;
- (ii)  $r \leq \mu((T_1, m_1)) \leq 2r$ ;
- (iii)  $v \in V(T_2)$ ; and
- (iv) every vertex that is marked in  $(T, m)$  is either marked in  $(T_1, m_1)$  or marked in  $(T_2, m_2)$ , but not in both. In other words, for every  $u \in V(T)$ ,
  - if  $v \in V(T_1) \cap V(T_2)$  then  $m(v) = 1 \Leftrightarrow m_1(v) = 1$  or  $m_2(v) = 1$  but not both;
  - otherwise, let  $i \in \{1, 2\}$  be the integer such that  $v \in V(T_i)$ . Then we have  $m(v) = m_i(v)$ .

We remark that because of (iv),  $\mu(T) = \mu(T_1) + \mu(T_2)$ . If for every  $v \in V(T)$ ,  $(T, m)$  has an  $r$ -good partition of root  $v$ , then  $T$  is said to have an  $r$ -good partition.

**Lemma 1.** *For every integer  $r > 0$  and every marked tree  $(T, m)$ , if  $\mu(T) \geq 2r$  then  $(T, m)$  has an  $r$ -good partition.*

*Proof.* Let  $r > 0$  be an integer. We prove this lemma by induction on the size of the tree.

*Base case:*  $|V(T)| = 0$ . Since  $2r \geq 2 > |V(T)|$ ,  $T$  does not have  $2r$  marked vertices and we are done.

*Induction step:* Assume that for every integer  $n' < n$ , every marked tree  $(T', m')$  on  $n'$  vertices and satisfying  $\mu((T', m')) \geq 2r$  has an  $r$ -good partition (induction hypothesis).

Let us prove that every marked tree on  $n$  vertices has a  $r$ -good partition if it has at least  $2r$  marked vertices. Let  $(T, m)$  be a tree on  $n$  vertices and let  $v$  be a vertex of  $T$ . We assume that  $\mu((T, m)) \geq 2r$ . We distinguish two cases.

- $\mu((T, m)) = 2r$ :

Let  $T_1 = T$ , let  $m_1 = m$ , let  $T_2 = (\{v\}, \emptyset)$ , and let  $m_2: V(T_2) \rightarrow \{0, 1\}$  be the function equal to 0 on every vertex of  $T_2$ . Remark that  $(E(T_1), E(T_2)) = (E(T), \emptyset)$  is a partition of  $E(T)$ ,  $T_2$  contains  $v$ , and as  $(T, m)$  contains (exactly)  $2r$  marked vertices, so does  $(T_1, m)$ . Consequently  $((T_1, m_1), (T_2, m_2))$  is an  $r$ -good partition of  $(T, m)$ .

- $\mu((T, m)) > 2r$ :

We distinguish different cases depending on the degree of the root  $v$  in  $T$ .

Case 1:  $\deg(v) = 1$ .

Let  $u$  be the neighbor of  $v$  in  $T$ , let  $T' = T \setminus \{v\}$ , and  $m' = m|_{V(T')}$ . Remark that  $\mu((T', m')) \geq 2r$  and  $|V(T')| = |V(T)| - 1$ . By induction hypothesis,  $(T', m')$  has an  $r$ -good partition  $((T'_1, m_1), (T'_2, m_1))$  of root  $u$ . We extend it to  $T$  by setting  $T_1 = T'_1$  and  $T_2 = (V(T'_2) \cup \{v\}, E(T'_2) \cup \{v, u\})$ . Notice that  $T_2$  contains  $v$ . As the subtree  $T'_1$  contains at least  $r$  and at most  $2r$  marked vertices (induction hypothesis), so does  $T_1$ . Also, remark that  $(E(T_1), E(T_2))$  is a partition of  $E(T)$  and that since  $u \in T'_2$ , the graph  $T_2$  is connected. Therefore the pair  $(T_1, T_2)$  is an  $r$ -good partition of  $T$ .

Case 2:  $\deg(v) = d > 1$ .

Let  $u_1, \dots, u_d$  be the neighbors of  $v$  in  $T$  and for every  $i \in \llbracket 1, d \rrbracket$ , let  $C_i$  be the connected component of  $T \setminus \{v\}$  that contains  $u_i$ . We also define, for every  $i \in \llbracket 1, d \rrbracket$ , the restricted marking function  $w_i = m|_{V(C_i)}$ .

Subcase (a): there exists  $i \in \llbracket 1, d \rrbracket$  such that  $\mu((C_i, w_i)) > 2r$ .

Let  $T' = (V(C_i) \cup \{v\}, E(C_i) \cup \{u, v\})$  and let  $m' = m|_{V(T')}$ . Remark that  $|V(T')| < |V(T)|$  and  $\mu((T', m')) > 2r$ . According to the induction hypothesis,  $(T', m')$  has an  $r$ -good partition  $((T_1, m_1), (T_2, m_2))$  of root  $u_i$ . Similarly as before, we can extend it into an  $r$ -good partition  $((T_1, m_1), (T_2, m_2))$  of

$(T, m)$ . This is done by setting:

$$\begin{aligned} T_1 &= T'_1, \\ m_1 &= m'_1, \\ T_2 &= (V(T'_2) \cup \{v\}, E(T'_2) \cup \{v, u_i\}), \text{ and} \\ m_2 &: \begin{cases} v \mapsto 0 \\ u \in V(T_2) \setminus \{v\} \mapsto m'_2(u) \end{cases} . \end{aligned}$$

Subcase (b): there exists  $i \in \llbracket 1, d \rrbracket$  such that  $r \leq \mu((C_i, w_i)) \leq 2r$ .

Let  $T_1 = C_i$  and  $T_2 = T[E(T) \setminus E(T_1)]$ . In this case,  $(E(T_1), E(T_2))$  is a partition of  $E(T)$  and  $T_2$  is connected since it contains  $v$ , the vertex which is adjacent to the  $C_j$ 's. Thus, if we set  $m_1 = m|_{V(T_1)}$  and  $m_2 = m|_{V(T_2)}$ ,  $((T_1, m_1), (T_2, m_2))$  is an  $r$ -good partition of  $(T, m)$ .

Subcase (c): for all  $i \in \llbracket 1, d \rrbracket$ ,  $\mu((C_i, w_i)) < r$ .

Let  $j = \min \left\{ j \in \llbracket 2, d \rrbracket, \sum_{i=1}^j \mu((C_i, w_i)) \geq r \right\}$ . We set:

$$\begin{aligned} T_1 &= (\cup_{i \in \llbracket 1, j \rrbracket} V(C_i) \cup \{v\}, \cup_{i \in \llbracket 1, j \rrbracket} (E(C_i) \cup \{v, u_i\})), \\ m_1 &: \begin{cases} v \mapsto 0 \\ u \in V T_1 \setminus \{v\} \mapsto m(u) \end{cases} , \\ T_2 &= T[E(T) \setminus E(T_1)], \text{ and} \\ m_2 &= m|_{V(T_2)}. \end{aligned}$$

By definition of  $j$ ,  $\mu((T_1, m_1)) \geq r$  and as for every  $i \in \llbracket 1, d \rrbracket$ ,  $\mu((C_i, w_i)) < r$  we also have  $\mu((T_1, m_1)) < 2r$ . As before, the pair  $((T_1, m_1), (T_2, m_2))$  is an  $r$ -good partition of  $(T, m)$ .

In conclusion, we proved by induction that for every integer  $r$ , every tree having at least  $2r$  marked vertices has an  $r$ -good partition.  $\square$

In the sequel we will deal with packings of the graph  $\theta_r$ , for  $r > 1$ . The following remark is important.

*Remark 1.* If  $G$  is not biconnected, the number of edge-disjoint models of  $\theta_r$  in  $G$  is equal to the sum of the number of edge-disjoint models of  $\theta_r$  in every biconnected component of  $G$ . This enables us to treat biconnected components separately.

**Lemma 2.** *Let  $k > 0, r > 0$  be two integers, and let  $G$  be a biconnected graph with  $\Delta(G) \geq 2kr$ . Then  $G$  contains  $k$  edge-disjoint models of  $\theta_r$ .*

*Proof.* As  $G$  is biconnected, the removal of a vertex  $v$  of maximum degree gives a connected graph. Let  $T$  be a minimal tree of  $G \setminus \{v\}$  spanning the neighborhood  $N_G(v)$  of  $v$ . We mark the vertices of  $T$  that are elements of  $N_G(v)$ : this gives the marking function  $m$

for  $T$ . Let us prove by induction on  $k$  that  $(T, m)$  has  $k$  edge-disjoint marked subtrees  $(T_1, m_1), \dots, (T_k, m_k)$ , each containing at least  $r$  marked vertices. If we do so, then we are done because  $\{\{v\}, T_i\}_{i \in \llbracket 1, k \rrbracket}$  is a collection of  $k$  edge-disjoint  $\theta_r$  models. In fact, as for every  $i \in \llbracket 1, k \rrbracket$ ,  $T_i$  contains  $r' \geq r$  vertices adjacent to  $v$  in  $G$ , contracting the edges of  $T_i$  in  $G[\{v\} \cup V(T_i)]$  gives the graph  $\theta_{r'}$ . Let  $r > 0$  be an integer.

*Base case  $k = 1$ :* Clear.

*Induction step  $k > 1$ :* Assume that for every  $k' < k$ , every tree with at least  $2k'r$  vertices marked has  $k'$  edge-disjoint subtrees, each with at least  $r$  marked vertices. Let  $(T, m)$  be a marked tree such that  $\mu((T, m)) \geq 2kr$ . According to Lemma 1,  $(T, m)$  has an  $r$ -good partition  $((T_1, m_1), (T'_1, m'_1))$  such that  $r \leq \mu((T_1, m_1)) \leq 2r$  and  $\mu((T'_1, m'_1)) = \mu((T, m)) - \mu((T_1, m_1)) \geq 2(k-1)r$ . By induction hypothesis,  $(T'_1, m'_1)$  has  $k-1$  edge-disjoint marked subtrees  $(T_2, m_2), \dots, (T_k, m_k)$  each containing at least  $r$  marked vertices. Remark that as all these trees are subgraphs of  $T'_1$ , which is edge-disjoint from  $T_1$  in  $T$ , they are edge-disjoint from  $T_1$  as well. Consequently,  $(T_1, m_1), (T_2, m_2), \dots, (T_k, m_k)$  is the family of edge-disjoint subtrees we were looking for.  $\square$

### 3.2. Bounding the treewidth

**Lemma 3.** *There is a function  $h_r(k) = O(kr^2 \text{polylog } kr)$  such that for every  $k$  and  $r$  positive integers and every graph  $G$ , if  $\mathbf{tw}(G) \geq h_r(k)$  then  $G$  contains at least  $k$  vertex-disjoint models of  $\theta_r$ .*

*Proof.* Let  $G$  be a graph and  $k, r$  be two positive integers. By Proposition 4, if  $\mathbf{tw}(G) \geq 2k^2r^2$ , then  $G$  contains  $k$  vertex-disjoint models of  $\theta_r$ . Therefore, we only have to consider the case where  $\mathbf{tw}(G) < 2k^2r^2$ .

We also define  $A$  and  $\alpha$  to be two positive real numbers such that  $f_{\text{Prop5}}(x) \leq A \log^\alpha x$  holds for large enough  $x$  (cf. Proposition 5 for the definition of  $f_{\text{Prop5}}$ ). Finally, let  $h_r(k) = 4kr^2 \cdot A \log^\alpha(2k^2r^2)$ . Remark that  $h_r(k) = O(kr^2 \text{polylog } kr)$ . We will show that graphs whose treewidth is at least  $h_r(k)$  contain  $k$  vertex-disjoint models of  $\theta_r$ . Let us assume that  $\mathbf{tw}(G) \geq h_r(k)$ . We thus have:

$$\begin{aligned} \mathbf{tw}(G) &\geq 4kr^2 \cdot A \log^\alpha(2k^2r^2) \\ &\geq 4kr^2 \cdot A \log^\alpha(\mathbf{tw}(G)) && \text{(as we assume } \mathbf{tw}(G) < 2k^2r^2) \\ \frac{\mathbf{tw}(G)}{A \log^\alpha(\mathbf{tw}(G))} &\geq 4kr^2 && \text{(because } A \log^\alpha(\mathbf{tw}(G)) \text{ is positive)} \\ \frac{\mathbf{tw}(G)}{f_{\text{Prop5}}(\mathbf{tw}(G))} &\geq k(2r)^2 && \text{(for big enough } \mathbf{tw}(G)). \end{aligned}$$

Notice that  $k$  and  $2r$  meet the conditions of Proposition 5. Consequently, there is a partition  $G_1, \dots, G_k$  of  $G$  into vertex-disjoint subgraphs such that  $\forall i \in \llbracket 1, k \rrbracket$ ,  $\mathbf{tw}(G_i) \geq 2r$ . By Proposition 3, each of these subgraphs contains a model of  $\theta_r$ . Consequently,  $G$  contains  $k$  vertex-disjoint models of  $\theta_r$ , as required.  $\square$

A very similar proof can be used to show the following lemma, using Proposition 6.

**Lemma 4.** *There is a function  $h_r(k) = O(k^3 r \text{polylog } kr)$  such that for every  $k$  and  $r$  positive integers and every graph  $G$ , if  $\mathbf{tw}(G) \geq h_r(k)$  then  $G$  contains at least  $k$  vertex-disjoint models of  $\theta_r$ .*

### 3.3. From vertices to edges

In this section, we show how an estimation of a vertex-Erdős-Pósa gap can be derived from the bound on the treewidth obtained in Section 3.2. The proof of the two following lemmata are inspired from the proof of [10, Lemma 2].

**Lemma 5** (adapted from Lemma 2 of [10]). *Let  $k, r$  be two positive integers and  $G$  a graph such that  $\mathbf{pack}_{\theta_r}^{\mathbf{v}}(G) = k$ . Then  $G$  has a  $(\mathbf{tw}(G) + 1)$ -separation triple  $(V_1, S, V_2)$  such that  $\frac{1}{3}k \leq \mathbf{pack}_{\theta_r}^{\mathbf{v}}(G[V_1]) \leq \frac{2}{3}k$  and  $\mathbf{pack}_{\theta_r}^{\mathbf{v}}(G[V_1]) + \mathbf{pack}_{\theta_r}^{\mathbf{v}}(G[V_2]) \leq k$ .*

*Proof.* Let  $(T, \mathcal{V})$  be an optimal nice tree decomposition of  $G$ . For all  $t \in V(T)$ , let  $H_t$  be the subset of  $V(G)$  equal to  $\left(\bigcup_{t' \in \text{desc}_T(t)} V_{t'}\right) \setminus V_t$ , that is, informally, the subset of vertices that are in bags *below*  $V_t$  but not in  $V_t$ . We also define the function  $p: V(T) \rightarrow \mathbb{N}$  as:  $\forall t \in V(T)$ ,  $p(t) = \mathbf{pack}_{\theta_r}^{\mathbf{v}}(G[H_t])$ , which counts the number of vertex-disjoint models of  $\theta_r$  in the subgraph of  $G$  induced by  $H_t$ .

*Remark 2.* The function  $p$  is nondecreasing along every path from a vertex of  $T$  to the root of  $T$ , because if a vertex  $t' \in V(T)$  is a child of a vertex  $t \in V(T)$ , then  $H_{t'} \subseteq H_t$ , and thus  $\mathbf{pack}_{\theta_r}^{\mathbf{v}}(G[H_{t'}]) \leq \mathbf{pack}_{\theta_r}^{\mathbf{v}}(G[H_t])$ .

*Remark 3.* As  $T$  is a nice decomposition of  $G$ , its vertices can be of four different types. We make remarks about the value taken by  $p$  depending on the type of the vertices:

**Base node  $t$ :**  $p(t) = 0$ , because since  $t$  has no descendant,  $H_t = \emptyset$ ;

**Introduce node  $t$  with child  $t'$ :** as the unique element of  $V_t \setminus V_{t'}$  cannot appear in the bags of  $\text{desc}_T(t')$  (by definition of a tree decomposition),  $H_t = H_{t'}$  and then  $p(t) = p(t')$ ;

**Join node  $t$  with children  $t_1$  and  $t_2$ :**  $H_t = H_{t_1} \cup H_{t_2}$ , but  $H_{t_1}$  and  $H_{t_2}$  are disjoint and there is no edge between the vertices of  $H_{t_1}$  and of  $H_{t_2}$  in  $G[H_t]$  (otherwise the set  $V_{t_1} = V_{t_2}$  would contain an endpoint of this edge, which also belongs to  $H_{t_1}$  or  $H_{t_2}$ , and this is contradictory). Thus there is no  $\theta_r$ -model in  $G[H_t]$  that uses (simultaneously) vertices of  $H_{t_1}$  and of  $H_{t_2}$ , and therefore  $p(t) = p(t_1) + p(t_2)$ .

Let  $t \in V(T)$  be a node such that  $p(t) > \frac{2}{3}k$  and such that for every child  $t'$  of  $t$ ,  $p(t') \leq \frac{2}{3}k$ . Let us make some claims about  $t$ .

Claim 1: such a  $t$  exists.

*Proof of Claim 1.* The value of  $p$  on the root  $r$  of  $T$  is  $k$  (because  $G[H_r] = G$ ) and according to the previous remark, the value of  $p$  on base nodes is 0. As  $p$  is nondecreasing on a path from a base node to the root (see Remark 2), such a vertex  $t$  exists.  $\diamond$

Claim 2:  $t$  is unique.

*Proof of Claim 2.* To show that  $t$  is unique, we assume by contradiction that there is another  $t' \in V(T)$  with  $t' \neq t$  and  $p(t') > \frac{2}{3}k$ , and such that for every child  $t''$  of  $t'$ ,  $p(t'') \leq \frac{2}{3}k$ . Three cases can occur:

- (i)  $t'$  is a descendant of  $t$ . However,  $p$  is nondecreasing along any path from a vertex to the root (Remark 2) and  $p(t') \geq \frac{2}{3}k$ , whereas the value of  $p$  for each child of  $t$  is at most  $\frac{2}{3}k$ : this is a contradiction.
- (ii)  $t$  is a descendant of  $t'$ . The same argument applies (symmetric situation).
- (iii)  $t$  and  $t'$  are not in the above situations. Let  $v$  be the least common ancestor of  $t$  and  $t'$ . As  $p$  is nondecreasing along any path from a vertex to the root, the child  $v_t$  (respectively  $v_{t'}$ ) of  $v$  whose  $t$  (respectively  $t'$ ) is descendant of should be such that  $p(v_t) > \frac{2}{3}k$  (respectively  $p(v_{t'}) > \frac{2}{3}k$ ). By definition of  $v$ , we have  $v_t \neq v_{t'}$ . As  $v$  is a join node,  $p(v) = p(v_t) + p(v_{t'}) > \frac{4}{3}k$ , which is impossible.

$\diamond$

Claim 3:  $t$  is either a forget node or a join node.

*Proof of Claim 3.* By definition of  $t$ , the value  $p(t)$  is different from the value(s) taken by  $p$  over the child(ren) of  $t$ . This can only occur in the cases of a join node or a forget node.  $\diamond$

We now present a  $(\mathbf{tw}(G) + 1)$ -separation triple  $(V_1, S, V_2)$  of  $G$  with the required properties.

**Case 1:**  $t$  is a forget node with  $t'$  as child.

Let  $S = V_{t'}$ ,  $V_1 = H_{t'}$ , and  $E_2 = V(G) \setminus (V_1 \cup S)$ .

**Case 2:**  $t$  is a join node with  $t_1, t_2$  as children.

As  $\frac{2}{3}k < p(t) = p(t_1) + p(t_2)$  (Remark 3), there is  $i \in \{1, 2\}$  such that  $p(t_i) \geq \frac{k}{3}$ . Let  $S = V_i$ ,  $E_1 = H_{t_i}$ , and  $E_2 = V(G) \setminus (V_1 \cup S)$ .

In both cases, we have:

- (i)  $\frac{1}{3}k \leq \mathbf{pack}_{\theta_r}^y(G[V_1]) \leq \frac{2}{3}k$  by definition of  $V_1$  and  $t$ ;
- (ii)  $(V_1, S, V_2)$  is a partition of  $V(G)$ ;
- (iii) there is no edge between a vertex in  $V_1$  and a vertex of  $V_2$  (intuitively,  $S$  separates  $V_1$  and  $V_2$ );
- (iv)  $k = \mathbf{pack}_{\theta_r}^y(G) \geq \mathbf{pack}_{\theta_r}^y(G[V_1]) + \mathbf{pack}_{\theta_r}^y(G[V_2])$ , because  $V_1$  and  $V_2$  are disjoint subsets of  $V(G)$ ; and

(v)  $|S| \leq \mathbf{tw}(G) + 1$ , because  $S$  is a bag of an optimal tree decomposition of  $G$ .

To see why (iii) is true, assume by contradiction that there are two vertices  $u \in V_1$  and  $v \in V_2$  such that  $\{u, v\} \in E(G)$ . Let  $s_0 \in V(T)$  be the child of  $t$  such that  $S = V_{s_0}$  (cf. the two different cases above). By definition of  $V_1$  there is a vertex  $s_1 \in V(T)$  of  $T$  in  $\text{desc}_T(s_0)$  whose bag  $V_{s_1}$  contains  $u$ . By definition of  $V_2$ , the vertex  $v$  does not belong to the bag  $V_{s_0}$  nor to a bag of a descendant of  $s_0$ . Let  $s_2$  be a vertex of  $T$  containing  $v$  and which is, according to the previous remark, not the bag of a descendant of  $s_0$  nor  $s_0$ .

As  $(T, \mathcal{V})$  is a tree decomposition of  $G$  and  $\{u, v\} \in E(G)$ , we have the following:

- there is a vertex  $s \in V(T)$  whose bag contains both  $u$  and  $v$ ;
- the subgraph of  $T$  induced by vertices whose bags contain  $u$  (respectively  $v$ ) is connected.

Consequently there is a path in  $T$  from  $s_1$  to  $s$  (respectively from  $s_2$  to  $s$ ) whose each bag contains  $u$  (respectively  $v$ ). As  $s$  is on the (only) path of  $T$  linking  $s_1$  to  $s_2$ , one of  $u, v$  belongs to the bag  $V_s$ . But this contradicts the fact that  $(V_1, S, V_2)$  is a partition of  $V(G)$ .

We conclude that  $(V_1, S, V_2)$  is a  $(\mathbf{tw}(G) + 1)$ -separation triple of  $G$  with the required properties.  $\square$

**Lemma 6** (adapted from Lemma 2 of [10]). *Let  $r \in \mathbb{N}^*$  and let  $h_r: \mathbb{N} \rightarrow \mathbb{N}$  be a function such that:*

- $\exists k_0 \in \mathbb{N}, \exists c \in ]0, 1[, \forall r \in \mathbb{N}^*, \forall k > k_0, 2h_r(\frac{2}{3}k) \leq c \cdot h_r(k)$ ; and
- for every graph  $G$ , if  $\mathbf{tw}(G) \geq h_r(k)$  then  $G \geq_m (k + 1) \cdot \theta_r$ .

Then there is a function  $f_r(k) = O(h_r(k))$  such that for every graph we have:

$$\mathbf{cover}_{\theta_r}^{\vee}(G) \leq f_r(\mathbf{pack}_{\theta_r}^{\vee}(G))$$

*Proof.* Let  $r \geq 2$  be an integer. We show by induction on  $k$  the following statement:

$$\text{if } \mathbf{pack}_{\theta_r}^{\vee}(G) = k \text{ then } \mathbf{cover}_{\theta_r}^{\vee}(G) \leq h_r(k) \cdot \sum_{i=0}^{\log_{3/2} k} c^i. \quad (2)$$

*Base case  $k = 0$ :* Clear.

*Induction step  $k > 0$ :* We assume that (2) holds for every positive integer  $k' < k$ . Let  $G$  be a graph such that  $\mathbf{pack}_{\theta_r}^{\vee}(G) = k$ . First, remark that  $\mathbf{tw}(G) < h_r(k)$ , otherwise by definition of  $h_r$  we would have  $\mathbf{pack}_{\theta_r}^{\vee}(G) > k$ . Thus, by Lemma 5  $G$  contains a  $h_r(k)$ -separation triple  $(V_1, S, V_2)$  such that  $\frac{1}{3}k \leq \mathbf{pack}_{\theta_r}^{\vee}(G[V_1]) \leq \frac{2}{3}k$  and  $\mathbf{pack}_{\theta_r}^{\vee}(G[V_1]) + \mathbf{pack}_{\theta_r}^{\vee}(G[V_2]) \leq k$ .

*Remark 4.* Since  $\mathbf{pack}_{\theta_r}^{\vee}(G[V_1]) + \mathbf{pack}_{\theta_r}^{\vee}(G[V_2]) \leq \mathbf{pack}_{\theta_r}^{\vee}(G)$ , there is a real number  $\alpha \in [\frac{1}{3}, \frac{2}{3}]$ , for which we have:

$$\begin{cases} \mathbf{pack}_{\theta_r}^{\vee}(G[V_1]) = \alpha \cdot \mathbf{pack}_{\theta_r}^{\vee}(G) \\ \mathbf{pack}_{\theta_r}^{\vee}(G[V_2]) \leq (1 - \alpha) \cdot \mathbf{pack}_{\theta_r}^{\vee}(G). \end{cases}$$

Notice that  $\max\{\alpha, 1 - \alpha\} \leq \frac{2}{3}$ .

The triple  $(V_1, S, V_2)$  is a partition of  $V(G)$ , so the following holds:

$$\begin{aligned} \mathbf{cover}_{\theta_r}^{\vee}(G) &\leq \mathbf{cover}_{\theta_r}^{\vee}(G[V_1]) + \mathbf{cover}_{\theta_r}^{\vee}(G[V_2]) + |S| \\ &\leq \mathbf{cover}_{\theta_r}^{\vee}(G[V_1]) + \mathbf{cover}_{\theta_r}^{\vee}(G[V_2]) + h_r(k) \\ &\leq h_r(\alpha k) \cdot \sum_{i=0}^{\log_{3/2} \alpha k} c^i \\ &\quad + h_r((1 - \alpha)k) \cdot \sum_{i=0}^{\log_{3/2} (1-\alpha)k} c^i + h_r(k) \quad (\text{induction hypothesis}) \\ &\leq (h_r(\alpha k) + h_r((1 - \alpha)k)) \cdot \sum_{i=0}^{\log_{3/2} \frac{2}{3}k} c^i + h_r(k) \quad (\text{Remark 4}) \\ &\leq 2 \cdot h_r\left(\frac{2k}{3}\right) \cdot \sum_{i=0}^{\log_{3/2} \frac{2}{3}k} c^i + h_r(k) \quad (\text{Remark 4}) \\ &\leq c \cdot h_r(k) \cdot \sum_{i=0}^{\log_{3/2} \frac{2}{3}k} c^i + h_r(k) \quad (\text{definition of } h_r) \\ &\leq h_r(k) \cdot \sum_{i=1}^{\log_{3/2} k} c^i + h_r(k) \\ &\leq h_r(k) \cdot \sum_{i=0}^{\log_{3/2} k} c^i. \end{aligned}$$

This concludes the induction step. Now, remark that since  $c \in ]0, 1[$ , the series  $\sum_{i=0}^{\infty} c^i$  converges to  $\frac{1}{1-c}$ . Hence, for every  $r \in \mathbb{N}^*$  the following inequality holds for every graph  $G$ :

$$\mathbf{cover}_{\theta_r}^{\vee}(G) \leq \frac{1}{1-c} \cdot h_r(\mathbf{pack}_{\theta_r}^{\vee}(G)),$$

as required. □

**Corollary 1.** *Let  $f_r$  be the vertex-Erdős-Pósa gap of  $\mathcal{M}(\theta_r)$ . Then we have*

- $f_r(k) = O(k^2 r^2 \text{polylog } kr)$ ;

- $f_r(k) = O(k^4 r \text{ polylog } kr)$ .

*These estimations follow from Lemma 6 and Propositions 5 and 6.*

The following lemma shows how to translate a vertex-Erdős-Pósa gap into an edge-Erdős-Pósa gap in the case of  $\theta_r$ . The main idea of the proof is that if the considered graph has small maximum degree, a small edge-hitting set can be constructed from a small vertex-hitting set. On the other hand, a big maximum degree forces a large packing of  $\theta_r$ -models.

**Lemma 7.** *If  $f_r$  is the vertex-Erdős-Pósa gap of  $\mathcal{M}(\theta_r)$ , then the edge-Erdős-Pósa gap of  $\mathcal{M}(\theta_r)$  is less than  $2kr \cdot f_r(k)$ .*

*Proof.* Let  $G$  be a graph, let  $r \geq 2$  be an integer and let  $f_r$  is the vertex-Erdős-Pósa gap of  $\mathcal{M}(\theta_r)$ . We want to prove that if  $G$  contains less than  $k$  edge-disjoint models of  $\theta_r$ , then it has a  $\theta_r$ -edge-hitting set of size less than  $2kr \cdot f_r(k)$ .

According to Remark 1, we can assume that  $G$  is biconnected. If it is not the case, we consider its biconnected components separately (if it has no biconnected component then the lemma is trivial).

First, remark  $\Delta(G) < 2kr$ , otherwise by Lemma 2  $G$  would contain at least  $k$  edge-disjoint  $\theta_r$ -models.

Notice that if  $G$  does not contain  $k$  edge-disjoint  $\theta_r$ -models, it does not contain  $k$  vertex-disjoint  $\theta_r$ -models either. Consequently, there is a set  $X \subseteq V(G)$  meeting every  $\theta_r$  model of  $G$  and such that  $|X| \leq f_r(k)$ . Let us consider the set  $Y \subseteq E(G)$  of edges incident to vertices of  $X$ , *i.e.*  $Y = \{\{u, v\} \in E(G), u \in X\}$ . Remark that as  $\Delta(G) < 2kr$ , we have  $|Y| \leq 2kr \cdot f_r(k)$ . Now, assume that there is a  $\theta_r$ -model in  $G$  not having edges in  $Y$ . None of its vertices is in  $X$ , which is contradictory. So  $Y$  is a  $\theta_r$ -edge hitting set of the required size. This concludes the proof.  $\square$

**Corollary 2.** *An edge-gap of  $O(k^3 r^3)$  for  $\mathcal{M}(\theta_r)$  can be derived from Proposition 2.*

*Proof of Theorem 1.* It follows from the application of Lemma 7 to the estimations of the vertex-Erdős-Pósa gap of  $\theta_r$  given in Corollary 1.  $\square$

#### 4. Further research

The main question, initiated in this paper, is whether for every planar graph  $J$ , the class  $\mathcal{M}(J)$  satisfies this edge variant of the Erdős-Pósa property. As for the vertex version, it is easy to see that the planarity of  $J$  is necessary. For instance, if  $J = K_5$ , consider as graph  $G$  an  $n$ -vertex toroidal wall, which is a 3-regular graph embeddable in the torus that contains  $K_5$  as a minor. One can check that  $G$  does not contain two edge-disjoint models of  $K_5$ , but  $\Omega(\sqrt{n})$  edges of  $G$  are needed in order to hit all its  $K_5$ -models.

Moreover, a second question is: when this property holds, does it hold with a polynomial gap for all graphs? Also, finding lower bounds on this gap for specific graphs is another interesting and complementary question. Let us mention that, as it is the case for the vertex version (see [5, 8]), for any non-acyclic planar graph  $J$  for which the edge variant of the Erdős-Pósa property holds for  $\mathcal{M}(J)$ , we have that  $f_{\mathcal{M}(J)}(k) = \Omega(k \log k)$ . Indeed, let  $G$  be an  $n$ -vertex cubic graph with treewidth  $\Omega(n)$  and girth  $\Omega(\log n)$  (such graphs are well-known to exist). Since  $J$  is planar, the treewidth of any graph excluding  $J$  as a minor is bounded by a constant [18], hence any set of edges of  $G$  meeting all models of  $J$  has size  $\Omega(n)$  (as the removal of an edge may decrease the treewidth by at most two). On the other hand, since  $J$  contains a cycle and the girth of  $G$  is  $\Omega(\log n)$ , any model of  $J$  in  $G$  contains  $\Omega(\log n)$  edges (assuming that  $J$  does not have isolated vertices), and therefore  $G$  contains  $O(n/\log n)$  edge-disjoint models of  $J$  (here we have used that the degree of  $G$  is bounded), easily implying that  $f_{\mathcal{M}(J)}(k) = \Omega(k \log k)$ . In particular, it holds that  $f_{\mathcal{M}(\theta_r)}(k) = \Omega(k \log k)$  for any  $r \geq 2$ , so a first avenue for further work in this direction is to optimize the gap function  $f_{\mathcal{M}(\theta_r)}(k)$  given in Theorem 1.

Finally, when the graphs  $G$  (in which the packings or coverings are taken) are restricted to classes of bounded degree, the proof of Lemma 7 can easily be adapted to prove that the bound of the vertex version also holds for the edge version.
